Abstract
Low level detection of 1,4-dioxane is required. The detection limits vary with regulatory requirements from state to state and country to country. As instrument sensitivity has improved, it has become possible to detect compounds at lower and lower levels. This application note investigates the detection of 1,4-dioxane down to a 0.02 ug/L level using an Agilent 240 Ion Trap in the EI/MS/MS mode.

Introduction
The US EPA has classified 1,4-dioxane as a probable human carcinogen. This compound is associated with a number of other health concerns ranging from skin, lung, and eye irritation, to headaches and anorexia. There are several exposure pathways, namely inhalation of vapors, ingestion of contaminated food and water, or dermal contact. 1,4-Dioxane has also been classified as an emerging contaminant.

Because of its widespread use as a chlorinated solvent stabilizer, 1,4-dioxane may be found in the presence of high concentrations of 1,1,1-trichloroethane.

In 2008, the EPA developed EPA Method 522 for the analysis of 1,4-dioxane in water to improve detection limits, precision, and accuracy. It describes a solid phase extraction of sample, followed by extract concentration to 1 mL, and injection into a GC/MS in selected ion monitoring (SIM) mode.

This application note shows the use of MS/MS easily meets the demands of EPA Method 522.
Experimental

Calibration standard solutions
A series of calibration standards to encompass the desired calibration range were prepared. The calibration standards contained varying amounts of 1,4-dioxane, with fixed amounts of both the Surrogate and the Internal Standard, prepared in DCM. The number of standards required was determined by the calibration range. Three standards were required for one order of magnitude, six standards for two orders of magnitude and nine standards for three orders of magnitude.

The calibration curve associated with this application note data contained nine standards with concentrations of 1,4-dioxane ranging from 0.001 µg/mL to 0.50 µg/mL. (This corresponds to a concentration range of 0.02–10 µg/L in the drinking water samples.) The lowest standard is ½ the level of the lowest concentration required by EPA Method 522.

The concentrations of both 1,4-dioxane-d8 (SUR) and THF-d8 (IS) were 0.200 µg/mL in each standard.

Calibration

Calibration curve
The GC/MS MassHunter Software was used to create a calibration curve for 1,4-dioxane using the Internal Standard calculation technique. Concentrations were determined through the use of a linear calibration curve. Because the surrogate is added to all samples and standards at a single concentration, the calibration for the surrogate was accomplished using the average response factor.

Calibration acceptance criteria
When quantitated using the calibration curve, each calibration point, except the lowest point, should quantitate within 80–120% of its true value. The lowest point should quantitate within 60–140% of its true value.

Experimental conditions
All analyses were performed on an Agilent 7890A GC System equipped with an Agilent 7693 Automatic Sampler and an Agilent 240 Ion Trap GC/MS in Electron Ionization (EI) mode. MS/MS was used to enhance selectivity and sensitivity.

Ion trap setup parameters for 522
Ion Trap temperature 200 °C
Manifold temperature 60 °C
Transferline temperature 250 °C
Autotune
Scan type EI/MS/MS

GC setup parameters for 522
Column 20 m × 150 µm, 0.84 µm VF-624
Flow column 0.5 mL/minute
Oven 35 °C hold for 1.0 minutes
7 °C/min to 90 °C no hold,
50 °C/min to 280 °C
Equilibrium/stabilization time 2 minutes

MS/MS setup

GC setup parameters for 522

- MMI Injector operated in the pulsed splitless mode
- Insert - 2 mm dimple liner (p/n 5190-2297)
- 200 °C isothermal
- Purge flow to split vent 60 mL/min at 0.5 minutes
- 2 µL injection volume

Results and Discussion

Calibration from 1–500 ng/mL
1-4 dioxane, shown is the 1.0 ng/mL level
Eight replicates at 1.0 ng/mL to determine the method detection limit (MDL), limit of quantitation (LOQ), and limit of detection (LOD) values

- MDL - 0.2353 ng/mL
- LOQ - 0.7849 ng/mL
- LOD - 0.2355 ng/mL
- Signal-to-noise (S/N) - 120.88
- Calculations were automatically done from the MassHunter Software
Conclusion

This application note presents a sensitive, selective, and robust method to determine 1-4 dioxane in samples using THF d-8 as an internal standard. For the analysis of 1-4 dioxane, the benefits of Agilent GC Quadrupole Ion Trap MS/MS capability cannot be underestimated.

In terms of reducing sample matrix interference, improving S/N, and coupling its high selectivity and sensitivity, the GC Quadrupole Ion Trap MS/MS provides a more confidence driven solution for the analysis of 1-4 dioxane.

GC Quadrupole Ion Trap MS/MS analysis has the potential to reduce false positive and negatives as well as providing an additional degree of confidence in the results obtained.

Using the optimized method listed above, a fast, targeted GC/MS/MS method can be used to solve the current analysis problem facing laboratories today.
